k-Selection; Median

- Select the k -th smallest item in list
- Naïve Solution
 - Sort;
 - pick the k -th smallest item in sorted list.
 $O(n \log n)$ time complexity
- Randomized solution: Average case $O(n)$
- Improved Solution: worst case $O(n)$

```
QuickSort(A, p, r)
  if (p < r) then
    q = Partition(A, p, r)
    QuickSort(A, p, q)
    QuickSort(A, q+1, r)
```

```
Partition(A, p, r)
  x = A[r]
  i = p-1
  for j = p to r-1 do
    if (A[j] <= x) then
      i++
      SWAP(A[i], A[j])
  SWAP(A[i+1], A[r])
  return i+1
```

Partition Procedure Revisited

- The Partition code can be rewritten so that it accepts another parameter, namely, the pivot value. Let's call this new variation as PivotPartition.
- This change does not affect its time complexity.
- RandomizedPartition as used in RandomizedSelect picks the pivot uniformly at random from among the elements in the list to be partitioned.

Randomized Selection

```
RandomizedSelect( $A, p, r, i$ )
    if ( $p = r$ ) then
        return  $A[p]$ 
     $q = \text{RandomizedPartition}(A, p, r)$ 
     $k = q - p + 1$ 
    if ( $i = k$ )
        return  $A[i]$ 
    else if ( $i < k$ )
        return RandomizedSelect( $A, p, q-1, i$ )
    else
        return RandomizedSelect( $A, q+1, r, i-k$ )
```

Randomized Selection: Rewritten

```
RandomizedSelect(A, p, r, i)
    if (p = r) then
        return A[p]
    Pivot = A[random(p,r)]
    q = PivotPartition(A, p, r, Pivot)
    k = q - p + 1
    if (i = k)
        return A[i]
    else if (i < k)
        return RandomizedSelect(A, p, q-1, i)
    else
        return RandomizedSelect(A, q+1, r, i-k)
```
